**ABSTRACT** The use of artificial intelligence (AI) in sensor analytics is entering a new era based on the use of ubiquitous embedded connected devices. This transformation requires the adoption of design techniques that reconcile accurate results with sustainable system architectures. As such, improving the efficiency of AI hardware engines as well as machine learning (ML) compatibility must be considered. In this paper, we present the Hybrid-Float6 (HF6) quantization and its dedicated hardware design. We propose an optimized multiply-accumulate (MAC) hardware by reducing the mantissa multiplication to a multiplexor-adder operation. We exploit the intrinsic error tolerance of neural networks to further reduce the hardware design with approximation. To preserve model accuracy, we present a quantization-aware training (QAT) method, which in some cases improves accuracy. We demonstrate this concept in 2D convolution layers. We present a lightweight tensor processor (TP) implementing a pipelined vector dot-product. For ML compatibility/portability, the 6-bit FP is wrapped in the standard FP format, which is automatically extracted by the proposed hardware. The hardware/software architecture is compatible with TensorFlow (TF) Lite. We evaluate the applicability of our approach with a CNN-regression model for anomaly localization in a structural health monitoring (SHM) application based on acoustic emission (AE). The embedded hardware/software framework is demonstrated on XC7Z007S as the smallest Zynq-7000 SoC. The proposed implementation achieves a peak power efficiency and acceleration of 5.7 GFLOPS/s/W and 48.3×, respectively.

**INDEX TERMS** Convolutional neural networks, structural health monitoring, hardware accelerator, TensorFlow Lite, embedded systems, FPGA, custom floating-point

## I. INTRODUCTION

THERE is a growing demand for ubiquitous AI sensor analytics. Industry 4.0 and smart city infrastructure leverage AI solutions to increase productivity and adaptability [1]. These solutions are powered by advances in ML, compute engines, and big data. Hence, improvements of these should be considered for research, as they are the machinery of the future.

Convolutional neural networks (CNNs) represent the essential building blocks in 2D pattern analytics. Sensor-based applications such as mechanical fault diagnosis [2], [3], structural health monitoring [4], human activity recognition (HAR) [5], hazardous gas detection [6] have been powered

by CNN models in industry and academia. CNN-based models, as one of the main types of artificial neural networks (ANNs), have been widely used in sensor analytics with automatic learning from sensor data [7]–[10]. In this context, CNN models are applied for automatic feature learning, usually, from 1D time series as well as for 2D time-frequency spectrograms. CNN models provide advantages such as local dependency, scale invariance, and noise resilience in analytics [11]. However, these models are computationally intensive and power-hungry. This is particularly challenging for low-power embedded applications in the field of Internet-of-Things (IoT).

For ML inference, dedicated hardware architectures are

typically used to enhance compute performance and power efficiency. In terms of computational throughput, graphics processing units (GPUs) offer the highest performance; in terms of power efficiency, ASIC and FPGA solutions are more energy efficient [12]. As a result, numerous commercial ASIC and FPGA accelerators have been proposed, targeting both high performance computing (HPC) for data-centers and embedded systems applications.

However, most FPGA accelerators have been implemented to target mid- to high-range FPGAs for computationally intensive CNN models such as AlexNet, VGG-16, and ResNet-18. The main drawbacks of these implementations are power supply demands, physical dimensions, heat sink requirements, air cooling, and a resulting high price. In some cases, these implementations are not feasible for ubiquitous low-power/resource-constrained applications.

To reduce the compute hardware for CNN inference there are two types of research [13]: the first one is deep compression including weight pruning, weight quantization, and compression storage [14], [15]; the second type of research corresponds to a more efficient data representation, also known as custom quantization for dedicated hardware implementation. In this group, hardware implementations with customized 8-bit floating-point computation have been proposed [13], [16], [17]. However, these architectures are inadequate for embedded applications, the target devices are high-end FPGA and PCIe devices.

Reducing the compute hardware with more aggressive quantization such as binary [18], ternary [19], and mixed precision (2-bit activations and ternary weights) [20] typically incur significant accuracy degradation for very low precisions, especially for complex problems [21].

In this paper, we present the Hybrid-Float6 quantization and its dedicated hardware design. In this concept, feature maps are represented by standard 32-bit FP and trainable parameters by 6-bit FP. To preserve accuracy, we introduce a quantization-aware training (QAT) method. To preserve model accuracy, we present a quantization-aware training method, which in some cases improves model performance. For ML compatibility/portability, the 6-bit FP is wrapped into the standard FP representation. The dedicated hardware design extracts the 6-bit format automatically and performs the computation. We propose a parameterized tensor processor implementing a pipelined vector dot-product with HF6. The 6-bit FP representation uses 4-bit exponent and 1-bit mantissa. This approach enables an optimized MAC design by reducing the mantissa multiplication to a mux-adder operation. We leverage the intrinsic error tolerance of ANN to further reduce the hardware design with approximation. This approach reduces latency, resource utilization, and power dissipation. The embedded hardware/software architecture is integrated with TensorFlow Lite using delegate interface to accelerate *Conv2D* tensor operations. We evaluate the applicability of our approach with a CNN-regression model and hardware design exploration for sensor analytics of SHM for anomaly localization. The embedded hardware/software

FIGURE 1. The workflow of our approach on embedded FPGAs.

framework is demonstrated on XC7Z007S as the smallest and most inexpensive Zynq SoC device, see Fig. 1. To the best of our knowledge, this is the first research addressing 6-bit floating-point quantization on CNN models and its dedicated hardware design.

Our main contributions are as follows:

- 1) We present the Hybrid-Float6 quantization and its dedicated hardware design. We propose an optimized hardware MAC by reducing the mantissa multiplication to a mux-adder operation. We exploit the intrinsic error tolerance of ANN to further reduce the hardware design with approximation. To preserve model accuracy, we present a quantization-aware training method, which in some cases improves accuracy.
- 2) We develop a custom hardware/software co-design framework for sensor analytics applications on low-power embedded FPGAs. This architecture integrates TensorFlow Lite.
- 3) We present a customizable tensor processor as a dedicated hardware for HF6. This design computes *Conv2D* tensor operations employing a pipelined vector dot-product with parametrized on-chip memory utilization. The compute engine can be implemented with standard floating-point (with FP Xilinx LogiCORE IPs) and HF6.
- 4) We demonstrate the potential of our approach with a CNN-regression model for anomaly localization in SHM based on AE. We address a hardware design exploration. We evaluate inference accuracy, compute performance, hardware resource utilization, and energy consumption.

The rest of the paper is organized as follows. Section II covers the related work; Section III introduces the background for *Conv2D* tensor operation and floating-point number representation; Section IV describes the system design of the hardware/software architecture and the quantized aware training method; Section V presents the experimental results thorough a design exploration flow; Section VI concludes the paper.

This work is available to the community as an open-source project at <https://github.com/YaribNevarez/tensorflow-lite-fpga-delegate.git>.

## II. RELATED WORK

In the literature we find plenty of hardware architectures for CNN accelerators implemented in FPGA. Most of the research implements fixed-point quantization, and very limited research focuses on FP. Moreover, to the best of our knowledge, there is no research work exploring FP inference for low-power embedded applications.

### A. HYBRID CUSTOM FLOATING-POINT

In [22], Liangzhen Lai et al. proposed a mixed data representation with floating-point for weights and fixed-point for activations. [22] demonstrated on SqueezeNet, AlexNet, GoogLeNet, and VGG-16 that reduced FP quantization (4-bit exponent and 3-bit mantissa) results in constant negligible accuracy degradation. In [23], Sean O. Settle et al. presented an 8-bit FP quantization scheme, which needs an extra inference batch to compensate for quantization error. However, [22] and [23] did not present a hardware architecture. In [17], Xiaocong Lian et al. proposed an accelerator with optimized block floating-point (BFP), in this design the activations and weights are represented by 16-bit and 8-bit FP formats, respectively. This design is demonstrated on Xilinx VC709 evaluation board. This implementation achieves throughput and power efficiency of 760.83 GOP/s and 82.88 GOP/s/W, respectively.

### B. LOW-PRECISION FLOATING-POINT

In [16], Chunsheng Mei et al. presented a hardware accelerator for VGG16 model using half-precision FP (16-bit). This design is demonstrated on Xilinx Virtex-7 (XC7VX690T) with PCIe interface. This implementation achieves throughput and power efficiency of 202.8 GFLOP/s and 18.72 GFLOP/s/W, respectively. In [13], Chen Wu et al. proposed a low-precision (8-bit) floating-point (LPFP) quantization method for FPGA-based acceleration. This design is demonstrated on Xilinx Kintex 7 and Ultrascale/Ultrascale+. This implementation achieves throughput and power efficiency of 1086.8 GOP/s and 115.4 GOP/s/W, respectively.

### C. LOW-POWER

Two research papers have been reported hardware accelerators targeting XC7Z007S. This is the smallest and most inexpensive device from Zynq-7000 SoC family. In [24], Paolo Meloni et al. presented a CNN inference accelerator for compact and cost-optimized devices. This implementation uses fixed-point for processing light-weight CNN architectures with a power efficiency between 2.49 to 2.98 GOPS/s/W. In [25], Chang Gao et al. presented EdgeDRNN, a recurrent neural network (RNN) accelerator for edge inference. This implementation adopts the spiking neural network (SNN) inspired delta network algorithm to exploit temporal sparsity in RNNs.

## III. BACKGROUND

### A. CONV2D TENSOR OPERATION

A convolutional layer aims to learn feature representations from an input layer. The convolution layer is made of convolution kernels that are used to compute feature maps. Each unit of a feature map is connected to a region of neighboring units on the input maps (from previous layer). Such a neighborhood of the previous layer is known as the receptive field of the unit. A new feature map can be obtained by first convolving the input maps with a learned kernel and then applying a nonlinear elementwise activation function to the convolved results. All spatial locations on the input maps share a kernel to generate a feature map. All feature maps are obtained by convolving several different kernels [26].

The 2D convolution process is performed by the *Conv2D* tensor operation, described in **Eq. (1)**, where  $h$  is the input tensor containing the feature maps,  $W$  is the convolution kernels (known as filters), and  $b$  is the bias vector for the output feature maps [27].  $K \times L \times M$  is the receptive field size,  $K \times L$  is the convolution kernel, and  $M$  is the number of input channels/feature maps. We denote *Conv* as *Conv2D* operator.

$$Conv(W, h)_{i,j,o} = \sum_{k,l,m}^{K,L,M} h_{(i+k,j+l,m)} W_{(o,k,l,m)} + b_o \quad (1)$$

### B. FLOATING-POINT NUMBER REPRESENTATION

The representation of every numerical value, in any number system, is made of an integer and a fractional part. The border that delimits them is called the radix point. The fixed-point format for representing numeric values derives its name from the fact that in this format, the base point is fixed at a certain position. For integer numbers, this position is at the right of the least significant digit.

In scientific computation, it is often necessary to represent very large and very small values. This is difficult to achieve using the fixed-point format because the bit size/width required to maintain both the desired precision and the desired range are very large. In such situations, FP formats are used to represent real numbers. Each FP number can be divided into three fields: sign  $S$ , exponent  $E$ , and mantissa  $M$ . Using the binary number system, it is possible to represent any FP number as:

$$(-1)^S \times 1.M \times 2^{E-B} \quad (2)$$

In FP representations the exponent is biased. This bias depends on the bit size of the exponent field in the particular format. This exponent bias is defined by **Eq. (3)**, where  $E_{size}$  is the exponent bit size.

$$B = 2^{E_{size}-1} - 1 \quad (3)$$

There is a natural trade-off between small bit size requiring fewer hardware resources and larger bit size providing higher precision. Within a given total bit size, it is possible to assign

various combinations of sizes to the exponent and mantissa fields, with wider exponents resulting in a higher range and wider mantissa resulting in better precision.

The most widely used format for FP arithmetic is the IEEE 754 standard [28]. The IEEE single-precision format (32-bit) is expressed by Eq. (2) with  $B = 127$ , 8 bits for the exponent and 23 bits for the mantissa, see Fig. 2(a). In FP formats, the numbers are normalized, the leading one is an implicit bit, and only the fractional part is explicitly stored in the mantissa field.

FIGURE 2. Floating-point number representation.

Reduced bit size than those specified in the IEEE 754 standard are often sufficient to provide the desired precision. Reduced designs require fewer hardware resources enabling low-power implementations. In custom hardware designs, it is possible to customize the FP format implemented. In later sections, we use the term  $EaMb$  to denote FP formats, where  $a$  and  $b$  are the exponent and mantissa bit size, respectively. For example,  $E4M1$  means 4-bit exponent and 1-bit mantissa, see Fig. 2(d).

There are three special definitions in IEEE 754 standard. The first is subnormal numbers when  $E = 0$ , then Eq. (2) is modified to Eq. (4). Infinity and not a number (NaN) are the other two special cases but are not used in our work.

$$(-1)^S \times 0.M \times 2^{1-B} \quad (4)$$

#### IV. SYSTEM DESIGN

The system design is a hardware/software co-design framework for low-power AI deployment. This architecture allows design exploration of dedicated hardware integrated with TensorFlow Lite on low-cost embedded FPGAs.

##### A. BASE EMBEDDED SYSTEM ARCHITECTURE

The base embedded system architecture implements a co-operative hardware-software platform. See Fig. 3. The embedded CPU delegates low-level compute-bound tensor operations to the TPs. The TPs employ AXI-Lite interface for configuration and AXI-Stream interfaces via Direct Memory Access (DMA) for data movement from DDR memory. Each

FIGURE 3. Base embedded system architecture.

TP asserts an interrupt flag once the job/transaction is complete. Interrupt events are handled by the embedded CPU to collect results and start a new transaction. The hardware architecture can vary its resource utilization by customizing the TPs prior to the hardware synthesis.

##### B. TENSOR PROCESSOR

The TP is a dedicated hardware module to compute tensor operations. This architecture implements high performance communication with AXI-Stream, direct CPU communication with AXI-Lite, and on-chip storage utilizing BRAM. This hardware architecture is implemented with high-level synthesis (HLS). The tensor operations are implemented based on the C++ TensorFlow Lite micro kernels. See Fig. 4.

The TP is an extensible hardware module that executes low-level tensor operations. In this paper, we focus on the *Conv2D* tensor operation that computes 2D convolution layers.

##### 1) Modes of operation

The TP has two modes of operation: *configuration* and *execution*.

- In *configuration* mode, the TP receives the tensor operation hyperparameters: stride, dilation, padding, offset, activation, depth-multiplier, input shape, filter shape, bias shape, and output shape. Afterwards, the TP receives filter and bias tensors, which are locally stored in BRAM. The filter and bias tensors are transferred with standard FP representation. Then, the TP extracts the 6-bit FP format for local on-chip storage.
- In *execution* mode, the TP executes the tensor operation according to the hyperparameters given in the configuration mode. During execution, the input and output tensors are moved from/to the off-chip memory via DMA.

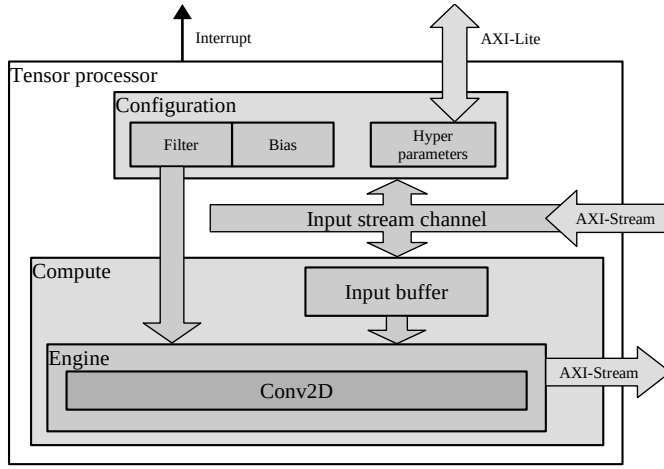

FIGURE 4. Hardware architecture of the proposed tensor processor.

## 2) Dot-product with hybrid floating-point

We implement the floating-point computation adopting the dot-product with hybrid custom floating-point [29]. The hardware dot-product is illustrated in Fig. 5 and Fig. 6(a). This design instantiates an HF6 MAC and an accumulator variable of 64-bit fixed-point with 23-bit fraction. During operation, the feature map and filter values are extracted from on-chip memory (BRAM). Both values have to be different than zero to enable the MAC operation. The result is biased by accumulating a denormalized bias value. Since the bias is stored with 6-bit FP, its fractional part has to be aligned with the 23-bit fraction of the accumulator, see Fig. 6(b). The ReLu activation is applied and the result is normalized to converted to IEEE 754 standard FP, see Fig. 6(c).

Rather than a parallelized structure, this is a pipelined hardware design suitable for resource-limited devices. The latency in clock cycles of this hardware module is defined by Eq. (5), where  $N$  is the vector length. This latency equation is obtained from the general pipelined hardware latency formula:  $L = (N - 1)II + IL$ , where  $II$  is the initiation interval, and  $IL$  is the iteration latency. Both  $II$  and  $IL$  are obtained from the high-level synthesis results. Both the exponent and mantissa bit widths of the filter and bias buffers are set to a 4-bit exponent and a 1-bit mantissa (E4M1), which corresponds to float6 quantization.

$$L_{hf} = N + 7 \quad (5)$$

## 3) Multiply-Accumulate

The multiply-accumulate operation calculates the product of two numbers and adds the result to an accumulator. In FP arithmetics, the size of a hardware multiplier scales with the size of the mantissas. In the case of HF6, the 6-bit FP representation allows optimization in the mantissa multiplication. The 1-bit mantissa enables efficient MAC implementations

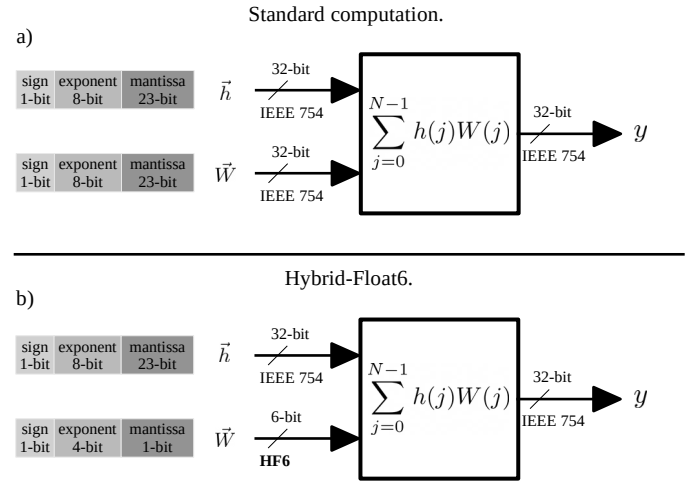

FIGURE 5. Dot-product hardware module with (a) standard floating-point and (b) Hybrid-Float6.

FIGURE 6. (a) Dot-product hardware module with Hybrid-Float6 MAC, (b) bias accumulation, (c) activation and normalization.

by reducing the mantissa multiplication to a multiplexed addition, see Fig. 7. The denormalized results are accumulated in a fixed-point accumulator. This approach reduces latency, energy consumption, and resource utilization.

## Hybrid-Float6 MAC

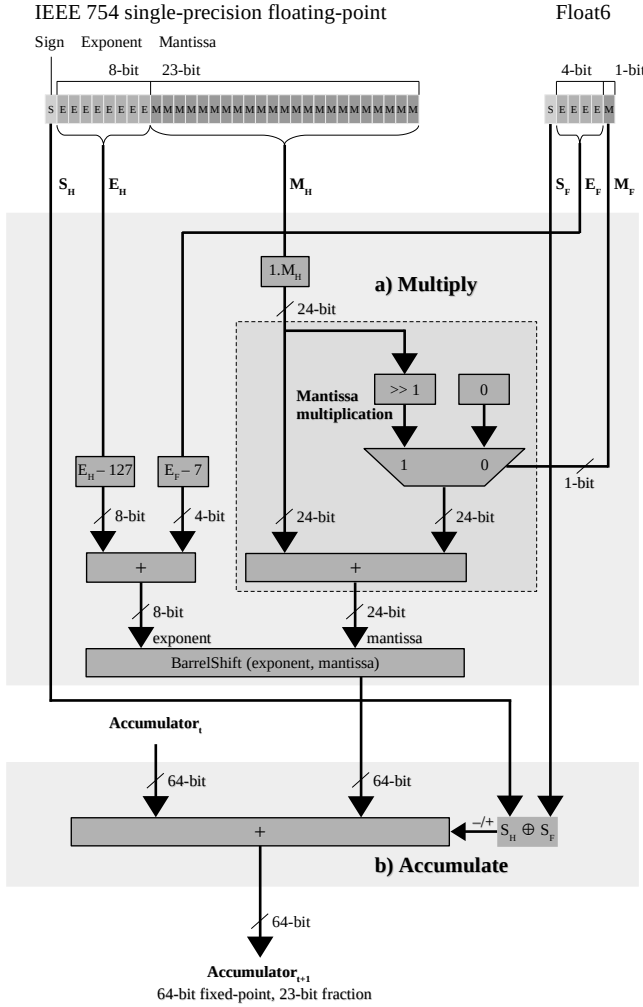

FIGURE 7. Hybrid-Float6 multiply-accumulate hardware design.

The Infinity and NaN special cases are not considered in this design since are not expected in ANN computation. For the subnormal case, the element-wise multiplication is disabled when having a zero entry and is approximated when having subnormal mantissa. The feature map values are considered zero when the exponent is zero ( $E_H = 0$ ). The filter values are considered zero when both exponent and mantissa are zero ( $E_F = 0 \wedge M_F = 0$ ). See Fig. 6(a). In the 6-bit FP, the 1-bit mantissa has one subnormal case, which is handled as a normalized case. This exploits the intrinsic error tolerance of ANN to reduce the hardware design.

The approximation error is defined by the difference between Eq. (2) and Eq. (4) when  $E = 0$  and  $M = 2^{-1}$ . The result defines the error as  $e = 2^{-B-1}$ . Then, from Eq. (3) with  $E_{size} = 4$ , we have  $B = 7$ . Hence,  $e = 3.9e-3$ . This error is produced when having the subnormal case  $E = 0$  and  $M = 2^{-1}$ , which corresponds to the value  $\pm 7.8e-3$  deviated to  $\pm 1.17e-2$ . This approximation leverages the intrinsic error tolerance of ANN to reduce hardware resource

FIGURE 8. Design parameters for on-chip memory buffers on the TP.

utilization and energy consumption [11].

## 4) On-chip memory utilization

The total on-chip memory utilization on the TP is defined by Eq. (6), where  $TP_B$  and  $V_M$  represent the tensor buffers and local variables (memory) required for the design, respectively. Eq. (7) defines the tensor buffers, where  $Input_M$  is the input buffer,  $Filter_M$  is the filter buffer,  $Bias_M$  is the bias buffer. The on-chip memory buffers are defined in bits. Fig. 8 illustrates the convolution operation utilizing the on-chip memory buffers.

$$TP_M = TP_B + V_M \quad (6)$$

$$TP_B = Input_M + Filter_M + Bias_M \quad (7)$$

The memory utilization of input buffer is defined by Eq. (8), where  $K_H$  is the height of the convolution kernel,  $W_I$  is the width of the input tensor,  $C_I$  is the number of input channels, and  $BitSize_I$  is the bit size of input tensor.

$$Input_M = K_H W_I C_I BitSize_I \quad (8)$$

The memory utilization of filter buffer is defined by Eq. (9), where  $K_W$  and  $K_H$  are the width and height of the convolution kernel, respectively;  $C_I$  and  $C_O$  are the number of input and output channels, respectively; and  $BitSize_F$  is the bit size of filter values.

$$Filter_M = C_I K_W K_H C_O BitSize_F \quad (9)$$

The memory utilization of bias buffer is defined by Eq. (10), where  $C_O$  is the number of output channels, and  $BitSize_B$  is the bit size of bias values.

$$Bias_M = C_O BitSize_B \quad (10)$$

As a design trade-off, Eq. (11) defines the capacity of output channels based on the given design parameters. The total on-chip memory  $TP_M$  determines the TP capacity.

$$C_O = \frac{TP_M - V_M - K_H W_I C_I BitSize_I}{C_I K_W K_H BitSize_F + BitSize_B} \quad (11)$$

The floating-point formats implemented in the TP are defined by  $BitSize_F$ ,  $BitSize_B$  and  $BitSize_I$ . The HF6 defines 6-bit for  $BitSize_F$  and  $BitSize_B$ , and 32-bit for  $BitSize_I$ . These are design parameters defined before hardware synthesis. This allows fine control of BRAM utilization, which is suitable for resource-limited devices.

### C. TRAINING METHOD

The models are trained and quantized in separate stages.

#### 1) Training with Iterative Early Stop

To achieve better performance on CNN-regression models, we implement a training procedure with iterative early stop cycle. This allows to reach better local minima. This is a four steps process:

- 1) A model is obtained with an initial training with standard early stop monitoring.
- 2) The model is iteratively re-trained with standard early stop to search for better local minima. In each early stop the Adam optimizer restarts the moving averages.
- 3) In case of a better local minimum, the base model is updated/saved and used for subsequent re-training iterations, otherwise it is discarded.
- 4) The cyclic process stops automatically with a given patience. This allows to set a maximum training iterations before the stop.

This method is described in **Algorithm 1**.

#### 2) Quantization Aware Training

The quantization aware training (QAT) method is integrated into the training process, this operates after each mini-batch update. The quantization is applied on the trainable parameters of convolution layers. This method is implemented as a callback function in the TensorFlow/Keras framework, see **Algorithm 2**.

The quantization method uses rounding strategy to reduce the FP representation. This maps the full precision FP values to the closest representable 6-bit FP values, see **Algorithm 3**. This method quantizes the filter and bias tensors of the convolution layers. We have observed that the exponent bit size plays a more predominant influence on the model accuracy than the mantissa bit size. In [22], Lai et al. demonstrated that 4-bit exponent is adequate and consistent across different networks (SqueezeNet, AlexNet, GoogLeNet, VGG-16). In this work, we investigate 4-bit exponent and 1-bit mantissa.

### D. EMBEDDED SOFTWARE ARCHITECTURE

The software architecture is a layered object-oriented application framework written in C++, see **Fig. 9**. A description of the software layers is as follows:

- *Application*: As the highest level of abstraction, this software layer implements the application invoking the ML library.
- *Machine learning library*: This layer consist of TensorFlow Lite for micro controllers. This offers a comprehensive high level API that allows ML inference.

nates of acoustic emissions based on piezoelectric vibrations. We compare quantitative and qualitative aspects of the analytics using floating-point 32-bit, fixed-point 8-bit, Hybrid-Logarithmic 6-bit, and Hybrid-Float6.

To demonstrate the proposed hardware concept, we deploy

the CNN model for low-power inference in the smallest Zynq SoC. We compare the performance of the TP implemented with standard FP (using Xilinx LogiCORE IPs) and Hybrid-Float6 architecture.

**A. SENSOR ANALYTICS APPLICATION**

The analytics model is designed to predict x- y- coordinates of acoustic emissions on a metal plate. The metal plate is in the presence of noise disturbance to simulate realistic conditions. In this subsection, we present the structure for experimental setup, data sets, and the CNN-regression model.

**1) Experimental Setup**

The experiment uses eight piezoelectric sensors (Vallen Systeme VS900) attached with magnetic holders on a metal plate (90 cm x 86.6 cm x 0.3 cm). The VS900 devices can operate either in active or passive mode. Six VS900 are used in passive mode as acoustic sensors and two in active mode to produce acoustic emissions. These acoustic emissions simulate anomalies on x- y- coordinates as well as the noise disturbance on the system. See Fig. 10(a). The acoustic emissions are labeled with their coordinates to create data sets.

**2) Data Sets**

The data sets are recorded applying pulses on the metal plate, the x- y- coordinates of these pulses are used as labels. The pulses for training and validation data sets are shown in Fig. 10(b) and Fig. 10(c), respectively. The pulses for training and validation data sets are mutually exclusive, this exclusion is represented by the cross symbols in Fig. 10(c). This creates a grid layout used to collect samples for the data sets. This grid is 10 x 10. This grid does not consider the four corners as they are used for magnetic holders.

In order to create reproducible acoustic emissions, we use 9-cycle sine pulse in a Hanning window with central frequency  $f_c$  (narrow-banded in the frequency domain). We assume guided Lamb waves based on the plate structure. The narrow-band behavior also reduces the dispersion of the acoustic emission waves [30]. The waveform can be expressed as a function of time  $t$  as follows:

$$x_{\text{pulse}}(t) = \frac{1}{2} \left( 1 - \cos \frac{f_c t}{5} \right) A_0 \sin f_c t. \quad (12)$$

To generate the data sets, we use slightly different pulse amplitudes and frequencies for excitation. The pulse frequency  $f_c$  is varied in 1 kHz steps between 300 kHz and 349 kHz and the amplitude  $A_0$  is varied in 0.1 V steps between 2.6 V and 3.5 V. This results in 500 different pulses for each of the excitation points.

The signals for labeled pulses and noise disturbance are generated by arbitrary waveform generators (AWGs). The sensor signals are recorded via a Vallen AMSY-6 measurement system with a resolution of 18 bits and a sampling rate of  $f_s = 10$  MHz. The disturbance signal is gaussian noise with amplitudes between 0-3 V. This noise is applied via the

**FIGURE 10.** Experimental setup for sensor analytics on structural health monitoring, all lengths are in meters (m).

piezoelectric device  $N$  at  $x = 0.227$  m and  $y = 0.828$  m, see **Fig. 10(a)**.

To obtain both time and frequency domain information, the sampled pulses are converted into the time-frequency domain using the Short-Time Fourier Transform (STFT). This is calculated as follows [31]:

$$\mathcal{F}_{m,k}^{\gamma} = \sum_{n=0}^{N-1} x[n] \cdot \gamma^*[n - m\Delta M] \cdot e^{\frac{-j2\pi kn}{N}} \quad (13)$$

Here  $x[n]$  describes a discrete-time signal and  $\gamma^*[n -$

**FIGURE 11.** Spectrograms of sensors  $S_1, S_2$  converted to grayscale for pulses at  $x = 0.105$  m,  $y = 0.109$  m with noise disturbance.

$m\Delta M] \cdot e^{\frac{-j2\pi kn}{N}}$  the time- and frequency-shifted window function inside the considered interval  $[0, N - 1]$ .  $\Delta M$  describes the time shift and  $N$  the transformation window. Since only discrete frequencies and time points are considered,  $m = 0, 1, \dots, M - 1$  is valid. This complex-valued STFT is converted to real numbers via the magnitude square for pictorial representation in a spectrogram  $\mathcal{S}_{m,k}$ :

$$\mathcal{S}_{m,k} = \left| \mathcal{F}_{m,k}^{\gamma} \right|^2 = \left| \sum_{n=0}^{N-1} x[n] \cdot \gamma^*[n - m\Delta M] \cdot e^{\frac{-j2\pi kn}{N}} \right|^2 \quad (14)$$

In addition, these spectrograms are scaled in decibels. The spectrogram in decibels  $\mathcal{S}_{m,k,\text{dB}}$  results in  $\mathcal{S}_{m,k,\text{dB}} = 20 \cdot \log_{10}(\mathcal{S}_{m,k})$ . For the conversion of the data, we use a signal length of  $400 \mu\text{s}$  ( $75 \mu\text{s}$  pretrigger and  $325 \mu\text{s}$  post trigger). Thus, the arrival times of the pulses are included in the spectrogram for all channels and labeled positions. We use a Blackman window function [32], a Fast Fourier Transform (FFT) length of 32 samples, and an overlap of 8 samples. The spectrograms are calculated for frequencies in the range of 100 kHz to 500 kHz. This results in a spectrogram with  $8 \times 16$  values (8 frequency values, 16 time values).

In order to generate larger data sets, we create four further variants with time shifts of  $15 \mu\text{s}/ 30 \mu\text{s}/ 45 \mu\text{s}/ 60 \mu\text{s}$ . Subsequently, all spectrograms are converted to grayscale with scaling between -100dB and -40dB, see **Fig. 11**. Overall, the data set has a size of  $500$  (pulses)  $\cdot 5$  (spectrograms)  $\cdot 6$  (listening sensors)  $\cdot 96$  (excitation points) = 1,440,000 images.

### 3) CNN-Regression Model

The data analytics is implemented with a CNN-regression model, see **Fig. 12**. The structure of the model is described below:

- Input tensor.** This is composed of spectrograms from the sensor signals. The tensor shape is defined by  $S \times T \times F$ , where  $S$  is the number of sensors, and  $T \times F$  is the time-frequency resolution of the spectrograms, see **Fig. 12(a)**.
- Feature extraction.** This is composed of three blocks of convolution, batch normalization, and max-pooling layers, see **Fig. 12(b)**. The number of channels in the convolution layers are defined by the hyper-parameters  $A, B$ , and  $C$ .

a) Input tensor

CNN-regression model

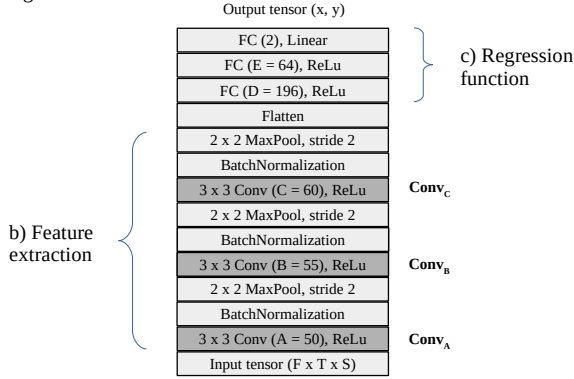

FIGURE 12. CNN-regression model for sensor analytics.

c) Regression function. This is an arbitrary function implemented with two fully connected layers and an output layer with linear activation, see Fig. 12(c).

## B. TRAINING

### 1) Base Model

The model in Fig. 12 is trained using Adam algorithm with iterative early stop. The Adam optimizer is configured with the default settings presented in [33]:  $\alpha = 0.001$ ,  $\beta_1 = 0.9$ ,  $\beta_2 = 0.999$ , and  $\epsilon = 1e-8$ . The training cycle patience is 10 iterations, the optimizer is executed with early stop patience of 10 epochs, and mini-batch size of 512 samples. This is applied using the method described in Algorithm 1 with  $N_I = 10$ ,  $N_E = 10$ ,  $B_{size} = 512$ .

The training results are illustrated in Fig. 13(a). In this experiment, the initial and the final models achieve  $MSE = 0.0135 \text{ m}^2$  and  $MSE = 0.0122 \text{ m}^2$ , respectively. The  $MSE$  is calculated with the Euclidean distance (loss) between the expected and the predicted coordinates. The initial model is obtained at the first early stop. In each stop, the moving averages of the Adam optimizer get initialized. This facilitates searching for better local minima. The model gets saved/updated when finding a better minimum.

The resulting model achieves  $MSE = 0.0122 \text{ m}^2$ , which corresponds to  $MAE = 0.0955 \text{ m}$ . See Fig. 14(a). In total, the training takes 379 epochs in 25 stops. The first stop takes 43 epochs for the initial model and subsequent training iterations take an average of 14 epochs. The total time is 53 minutes using a PC with AMD Ryzen 5 5600H and NVIDIA GeForce RTX 3050.

a) Training with iterative early stop.

b) Quantization aware training

FIGURE 13. Training results.

### 2) TensorFlow Lite 8-bit quantization

This integer quantization is an optimization method that converts 32-bit FP numbers (such as weights and activations) to 8-bit fixed-point numbers. This quantization scheme allows inference to be carried out using integer-only arithmetic [30].

The base model is quantized using the TensorFlow Lite library with integer-only quantization settings. The filter and bias tensors are represented by 8-bit and 32-bit signed integers, respectively. The input and output activation tensors are represented by 8-bit signed integer. For convolution layers, this quantization includes two additional tensor coefficients (output-multiplier and output-shift). These tensors are the same shape as the bias tensor and represented by 32-bit signed integers as well.

The fixed-point model achieves  $MSE = 0.0122 \text{ m}^2$  and  $MAE = 0.0952 \text{ m}$ . See Fig. 14(b). The  $MAE$  obtains a reduction of 0.31% compared to the base model. We attribute this to the regularization effect.

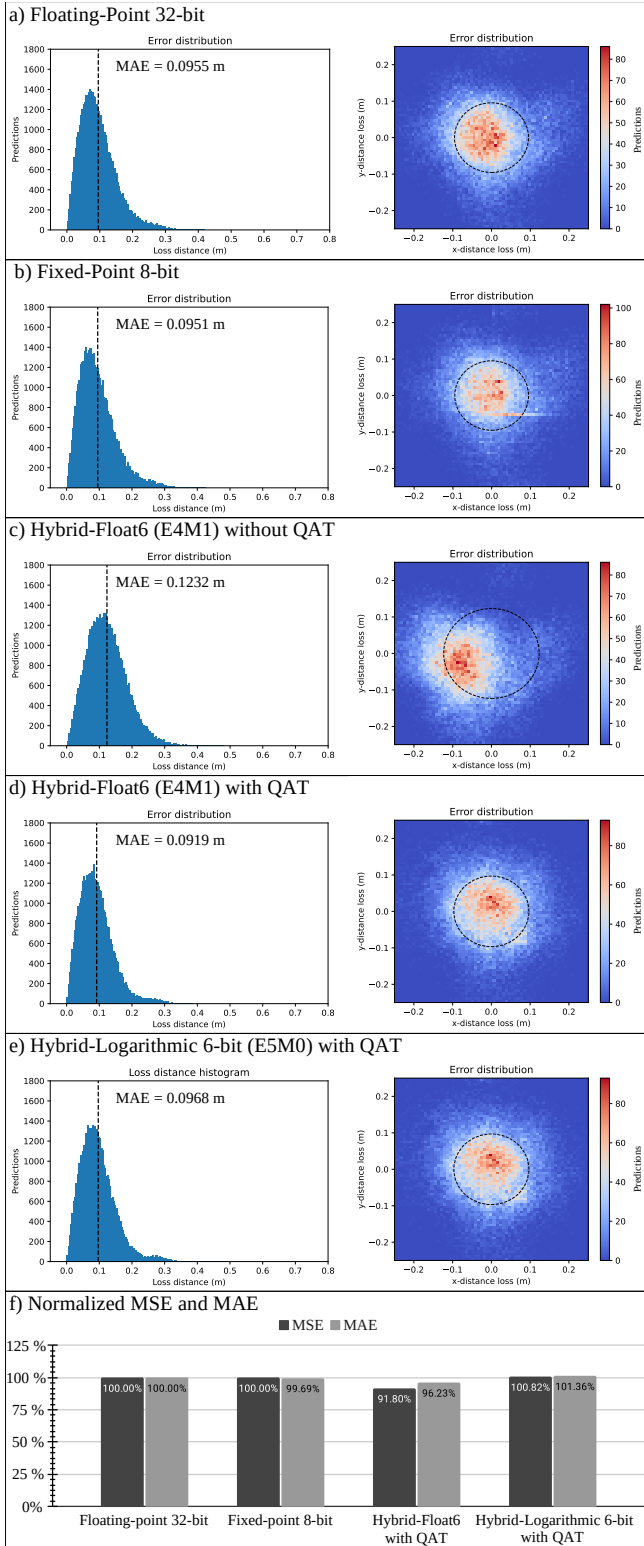

FIGURE 14. Performance of the model with different data representations.

### 3) Quantization Aware Training for Hybrid-Float6

The QAT is a post-training step. We run this method during two epochs with mini-batch size of 10 samples with 4-bit

exponent and 1-bit mantissa as parameters. This is applied using the method described in **Algorithm 2** with  $N_{ep} = 2$ ,  $B_{size} = 10$ ,  $E_{size} = 4$ ,  $M_{size} = 1$ .

The QAT is illustrated in **Fig. 13(b)**. First, the model gets quantized with HF6 format before starting QAT, this obtains  $MSE = 0.0188 \text{ m}^2$  and  $MAE = 0.1232 \text{ m}$ . This illustrates the inference of the base FP model (without QAT) on HF6 hardware. See **Fig. 14(c)**. Then, after QAT, the final model achieves  $MSE = 0.0112 \text{ m}^2$  and  $MAE = 0.0919 \text{ m}$ . This corresponds to an error reduction of 8.2% and 3.77%, respectively. See **Fig. 14(d)**. The QAT time is 185 minutes.

### 4) Quantization Aware Training for Hybrid-Logarithmic 6-bit

For the sake of quality comparison, we generate the model with 6-bit logarithmic quantization on convolution parameters, see **Fig. 2(e)**. This quantization matches the bit size of HF6. We run the QAT on the base model with hybrid logarithmic parameters. Then, the filter and bias tensors of convolution layers are represented by 6-bit signed logarithmic. This is applied using the method described in **Algorithm 2** with  $N_{ep} = 2$ ,  $B_{size} = 10$ ,  $E_{size} = 5$ ,  $M_{size} = 0$ .

In this case, the model gets quality degradation. The model reaches  $MSE = 0.0123 \text{ m}^2$  and  $MAE = 0.0968 \text{ m}$ , which correspond to an error increase of 0.82% and 1.36%, respectively. See **Fig. 14(e)**.

A summary of inference with different data representations is presented in **Fig. 14(f)**.

## C. HARDWARE DESIGN EXPLORATION

The proposed hardware/software co-design is demonstrated on the Zynq-7007S system-on-chip (SoC) on the MiniZed development board. This SoC integrates a single ARM Cortex-A9 processing system (PS) and a programmable logic (PL) equivalent to Xilinx Artix-7 (FPGA) in a single chip [34]. The Zynq-7007S SoC architecture maps the custom logic and software in the PL and PS, respectively.

In this platform, we implement the proposed hardware/software architecture to deploy the sensor analytics application. The desired model is converted to TensorFlow Lite (floating-point) and deployed on the SoC as a hex dump in a C array, this is used for the embedded software build. The Zynq-7007S SoC performs inference running TensorFlow Lite on the PS. The computational workload of convolution layers is delegated to the dedicated hardware.

### 1) Benchmark on Embedded CPU

We explore the performance of the embedded CPU for inference without hardware acceleration. In this case, TensorFlow Lite creates the CNN as a sequential model that allocates all computation to the CPU (ARM Cortex-A9) at 666 MHz and power dissipation of 1, 187 W.

The compute performance and run-time inference of the CPU are shown in **Tab. 2(a)** and **Fig. 16(a)**, respectively.

## 2) Benchmark on Tensor Processor with Standard Floating-Point Hardware using Xilinx LogiCORE IP

For this design, we implement the TP with standard FP hardware prior synthesis. The design parameters are:

- Max convolution kernel size:  $K_W = K_H = 3$ .
- Max input tensor width:  $W_I = 16$ .
- Max input and output channels:  $C_I = 55, C_O = 60$ .
- Filter and bias bit size:  $BitSize_F = BitSize_B = 32$ .
- Input tensor bit size:  $BitSize_I = 32$ .

Using equations from Section IV-B4, the on-chip memory buffer utilization are  $Input_M = 84,480b$ ,  $Filter_M = 950,400b$ , and  $Bias_M = 1,920b$ . Hence, the required on-chip memory buffer size is  $TP_B = 1,036,800b$ .

The post-implementation resource utilization and power dissipation are presented in **Tab. 1(a)**. The complete hardware platform utilizes 83% of BRAM, this includes the on-chip memory requirements of the TP, DMA, and AXI interconnects. The total available on-chip memory (BRAM) on the Zynq-7007S SoC is 1.8Mb. The estimated power dissipation of the TP is 85 mW at 200 MHz (this estimation is provided by Xilinx Vivado).

**TABLE 1.** Resource utilization and power dissipation on the Zynq-7007S SoC.

TP engine	Post-implementation resource utilization				Power (W)
	LUT	FF	DSP	BRAM 36Kb	
(a) Floating-Point	5,578 39%	8,942 31%	23 35%	41.5 <b>83%</b>	1.429
(b) Hybrid-Float6	7,313 51%	10,330 36%	20 30%	15 <b>30%</b>	1.424

The compute performance and inference schedule of the model on this hardware implementation are shown in **Tab. 2(b)** and **Fig. 16(b)**, respectively. In this implementation, TensorFlow Lite delegates computation of *Conv2D* tensor operations to the TP.

The implementation of the dot-product with standard FP engine (IEEE 754 arithmetic) utilizes proprietary multiplier and adder FP operator cores. Vivado HLS implements FP arithmetic operations by mapping them onto Xilinx LogiCORE IP cores, these FP operator cores are instantiated in the resultant RTL [35]. In this case, the implementation of the dot-product with the standard FP computation reuses the multiplier and adder cores in different compute sections of the TP. The post-implementation resource utilization and power dissipation of the floating-point operator cores are shown in **Tab. 3**.

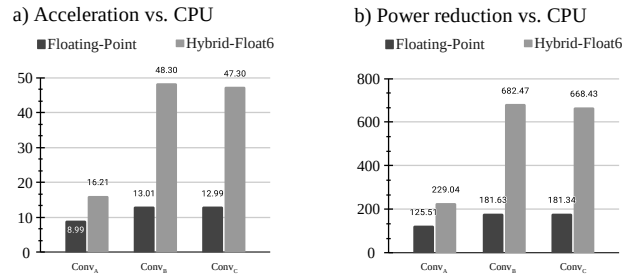

## 3) Tensor Processor with Hybrid-Float6 Hardware

To demonstrate the proposed design, the TP with HF6 hardware restates the standard FP design parameters with the following customization for the FP 6-bit quantization in filter and bias:  $BitSize_F = BitSize_B = 6$ .

Using equations from Section IV-B4, the on-chip memory requirements are  $Input_M = 84,480b$ ,  $Filter_M = 178,200b$ ,  $Bias_M = 360b$ . Hence, the required on-chip memory buffer size is  $TP_B = 263,040b$ .

**TABLE 2.** Compute performance of the CPU and TP on each Conv2D tensor operation. This table presents: tensor operation, computational cost in mega floating-point operations (MFLOP), latency, throughput, power efficiency, and estimated energy consumption as the energy delay product (EDP).

Operation	MFLOP	t (ms)	MFLOP/s	MFLOP/s/W	EDP (mJ)
<b>a) CPU (ARM Cortex-A9) @666MHz, 1.187 W</b>

Conv <sub>B</sub>	1.584	4.41	358.94	4,273.09	0.37
Conv <sub>C</sub>	0.475	0.99	482.44	5,743.29	0.08

**FIGURE 15.** Inference acceleration and power reduction on the TP with floating-point and HF6 vs. CPU on the Zynq-7007S SoC.

**TABLE 3.** Resource utilization and power dissipation of multiplier and adder floating-point (IEEE 754) operator cores (Xilinx LogiCORE IP).

Core operation	DSP	FF	LUT	Latency (clk)	Power (mW)
Multiplier	3	151	325	4	7
Adder	2	324	424	8	6

The post-implementation resource utilization and power dissipation are presented in **Tab. 1(b)**. The complete hardware platform utilizes 30% of BRAM, this includes the on-chip memory requirements of the TP, DMA, and AXI interconnects. The estimated power dissipation of the TP is 84 mW at 200 MHz (this estimation is provided by Xilinx Vivado).

The compute performance and inference schedule of the model on this hardware implementation are shown in **Tab. 2(c)** and **Fig. 16(c)**, respectively. **Fig. 15** presents a comparison of the acceleration and the reduction of power dissipation between standard FP and HF6 hardware implementations.

This deployment does not require model parameter extraction/treatment. The 6-bit FP representation is wrapped into the standard FP. The dedicated hardware design extracts the 6-bit format automatically and performs computation.

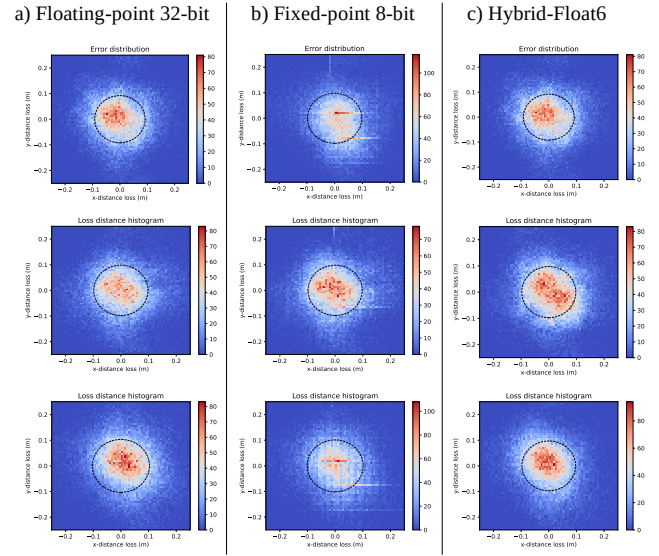

## D. DISCUSSION

**FIGURE 16.** Run-time inference of TensorFlow Lite on the Zynq-7007S SoC. (a) CPU ARM Cortex-A9 at 666 MHz, (b) cooperative CPU + TP with floating-point Xilinx LogiCORE IP at 200 MHz, and (c) cooperative CPU + TP with Hybrid-Float6 at 200 MHz.

### 1) Training and Quantization

The training with iterative early stop obtains a model with enhanced accuracy than standard early stop. This method iteratively resets the moving averages of Adam's optimizer,

**FIGURE 17.** 2D error distribution of three CNN-regression models.

which helps to find better local minima. This iterative search is suitable for models with low computational cost.

The TensorFlow Lite 8-bit quantization preserves the overall model accuracy. In some cases, the associated regularization effect can improve the accuracy. However, the error distribution in CNN linear regressions gets slightly degraded. **Fig. 17(b)** shows this effect on three different models, where vertical and horizontal patterns appear in the error distribution of fixed-point quantization. We attribute this effect to the 8-bit resolution in the activation maps. In the case of HF6 quantization, the activation maps are represented by FP preventing this degradation.

The proposed 6-bit FP representation (E4M1) in convolution parameters improves latency, hardware area, and power dissipation, while preserving model accuracy. In our application, this number format produces better results than the 6-bit logarithmic representation (E5M0). This is demonstrated in **Fig. 14(d)** and **Fig. 14(e)**.

Applying HF6 quantization on ALL-CNN-C [36] produces an accuracy degradation of 1.39% and 0.11% with QAT. While applying 6-bit logarithmic produces a degradation of 11.18% and 7.22% with QAT.

### 2) Implementation and Performance

The proposed HF6 implementation reduces on-chip memory and DSP utilization while slightly increasing FF and LUT compared to the standard FP implementation. See **Tab. 1** and **Fig. 18**. The HF6 logic is implemented using FF and LUT, while the FP logic is implemented using Xilinx LogiCORE IPs with DSPs.

The compute performance of the CPU and TP on each convolution layer of the model is presented in **Tab. 2** and **Fig. 15**. The peak acceleration and power efficiency of the TP with standard FP is  $13\times$  and 1,558.13 MFLOPS/s/W, respectively. The peak acceleration and power efficiency of

the TP with HF6 is  $48.3\times$  and  $5,743.29$  MFLOPS/s/W, respectively. The HF6 hardware demonstrates an improvement of  $3.7\times$  in acceleration and power efficiency with respect to the standard FP hardware. See Fig. 15. The estimated power dissipation on the SoC is presented in Fig. 19. This shows a very similar breakdown of power dissipation in both implementations. However, the energy efficiency is increased due to the reduced latency in HF6 hardware. A comparison of related work is presented in Tab. 4.

FIGURE 18. Hardware resource utilization on the Zynq-7007S SoC.

FIGURE 19. Estimated power dissipation on the Zynq-7007S SoC with PS at 666 MHz and PL at 200 MHz.

The run-time inference of TensorFlow Lite on the SoC is illustrated in Fig. 16. This shows the convolution layers as the compute-bound operations. The proposed embedded platform is a cooperative system where the convolution operations are delegated to the dedicated hardware accelerator. The ARM CPU obtains a latency of 387 ms (2.58 FPS). The platform with standard FP hardware obtains a latency of 48 ms (20.8 FPS), while the implementation with HF6 obtains a latency of 27.9 ms (35.84 FPS). These represent an overall acceleration of  $8\times$  and  $13.87\times$  over the CPU, respectively.

For ML compatibility/portability, the 6-bit FP is wrapped into the standard FP representation. The dedicated hardware design extracts the 6-bit format automatically and performs the computation.

### 3) SoC Design and Compatibility

The proposed design is an alternative for low-power FP inference. The system runs as a cooperative hardware/software mechanism. This architecture delegates compute-bound tensor operations to a hardware accelerator.

The hybrid 32-bit FP and 6-bit FP quantization enables high quality of results and backward ML compatibility. Backwards ML compatibility gives portability from training to inference. This enables to run inference of HF6 quantized models on standard FP hardware and vice versa. Running inference of models without QAT allows rapid deployment; however, this will incur in accuracy degradation, see Fig. 14(c).

### 4) Future Work

To reduce energy consumption, activation maps can be represented by Bfloat16. This would reduce hardware resource utilization, memory footprint, and data transfer. To increase performance, this implementation would require matching computational throughput with memory bandwidth using systolic arrays to replace the pipeline structure.

## VI. CONCLUSIONS

In this paper, we present the Hybrid-Float6 quantization for floating-point CNN hardware acceleration. Feature maps and weights are represented by 32-bit and 6-bit floating-point, respectively. The 6-bit floating-point format is composed of 1-bit sign, 4-bit exponent, and 1-bit mantissa. The 1-bit mantissa enables low-power multiply-accumulate implementations by reducing the mantissa multiplication to a multiplexer-adder operation. We exploit the intrinsic error tolerance of neural networks to further reduce the hardware design with approximation. This approach improves latency, hardware area, and energy consumption. To preserve accuracy, we introduce a quantization aware training method that, in some cases, improves accuracy. We present a lightweight tensor processor implementing a pipelined vector dot-product. For ML compatibility/portability, the 6-bit FP is wrapped in the standard floating-point format, which is automatically extracted by the proposed hardware. The hardware/software architecture is compatible with TensorFlow Lite. We evaluate the applicability of our approach with a CNN-regression model for anomaly localization in a structural health monitoring application based on acoustic emissions. The embedded hardware/software framework is demonstrated on XC7Z007S as the smallest Zynq-7000 SoC. The proposed hardware achieves a peak power efficiency and acceleration on convolution layers of  $5.7$  GFLOPS/s/W and  $48.3\times$ , respectively.

YARIB NEVAREZ received the B.E. (Hons) degree in electronics from the Durango Institute of Technology, Durango, Mexico, in 2009, and the M.Sc. degree in Embedded Systems Design from the University of Applied Sciences Bremerhaven, Bremen, Germany, in 2017. He is currently pursuing a PhD degree with the Institute of Electrodynamics and Microelectronics, University of Bremen, Germany. His research interest is focused mainly on System-on-Chip architectures and hardware implementation for deep learning accelerators in Embedded Systems. During his professional experience, he served as a Senior Embedded Software Engineer at Texas Instruments, IBM, Continental Automotive, TOSHIBA, and Carbon Robotics. He has designed and developed software architectures for graphic calculators, automotive systems, robotic drivers, and more.

WANLI YU received the B. S. degree in information engineering and the M. S. degree in signal and information processing from the China University of Mining and Technology, Xuzhou, China, in 2009 and 2012, respectively and the PhD degree from the University of Bremen, Germany, in 2018.

He is currently a Post-Doctoral Researcher with the Institute of Electrodynamics and Microelectronics, University of Bremen. His research interests include sensor networks, Internet of Things, network performance optimization, energy aware task allocation and scheduling, mobile edge/fog computing, convex optimization, machine learning and nature-inspired population-based optimization.

ANDREAS BEERING received his B.Sc. and M.Sc. degree in Electrical and Information Engineering from the University of Bremen, Germany, in 2015 and 2017, respectively. He is currently working towards a Ph.D. degree at the Institute of Electrodynamics and Microelectronics at the University of Bremen, Germany. His research interests focus mainly on signal processing and classification of vibration signals. In addition to the analysis of passive acoustic emission for monitoring gearboxes and processes, the second focus lies on active ultrasonic investigations. In this context, ultrasonic waveforms for monitoring overmoulding processes are being investigated.

YIZHI CHEN received the B.E. degree in Electronic and Information Engineering from Wuhan University, China, in 2017 and he received the M.S. degree in Communication and Information Technology from the University of Bremen, Germany, in 2021. Currently, he is working as a Ph.D. student at the Division of Electronics and Embedded Systems, Department of Electrical Engineering, School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology,

Sweden. His research interests include hardware accelerator for ML, fault-tolerant hardware for neural networks, Network-on-Chip, and approximate computing.

AMIR NAJAFI

ARDALAN NAJAFI

KARL-LUDWIG KRIEGER received his Ph.D. degree in Electrical Engineering in 1999 from the University of Bremen, Germany. Dr. Krieger worked from 1998-2009 as a manager in the field of function and algorithm development for powertrain systems at Daimler AG in Stuttgart. Since 2009 he has been a full professor for the chair of Electronic Vehicle and Mobility Systems at the University of Bremen, Germany. The research focus of his chair is primarily on the analysis of vibration and ultrasound signals in different application fields, for example, passenger cars, heavy-duty trucks, mobile working machines or industrial machines. Further research priorities of the chair are near-infrared spectral sensors and capacitive sensor systems for different fields of application. These research topics are worked on in close cooperation with leading industrial partners and are mainly financed from third-party funds.

ALBERTO GARCIA-ORTIZ obtained the diploma degree in Telecommunication Systems from the Polytechnic University of Valencia (Spain) in 1998. After working for two years at Newlogic in Austria, he started the Ph.D. at the Institute of Microelectronic Systems, Darmstadt University of Technology, Germany. In 2003, he received from the Department of Electrical Engineering and Information Technology of the university the Ph.D. degree with "summa cum laude."

From 2003 to 2005, he worked as a Senior Hardware Design Engineer at IBM Deutschland Development and Research in Böblingen. After that he joined the start-up AnaFocus (Spain), where he was responsible for the design and integration of AnaFocus' next generation Vision Systems-on-Chip. He is currently full professor for the chair of integrated digital systems at the university of Bremen. Dr. Garcia-Ortiz received the "Outstanding dissertation award" in 2004 from the European Design and Automation Association. In 2005, he received from IBM an innovation award for contributions to leakage estimation. Two patents are issued with that work. He serves as editor of JOLPE and is reviewer of several conferences, journals, and European projects.

His interests include low-power design and estimation, communication-centric design, SoC integration, and variations-aware design.
